**DOI:** <https://doi.org/10.33545/26633582.2023.v5.i2a.95>

### Abstract

This paper compares the efficiency of two popular feature extraction methods Principal Component Analysis and Local Binary Pattern using two different iris databases CASIA and UBIRIS. For classification, Support Vector Machine has been used. The models were tested using 200 iris images. The Receiver Operating Characteristic Curve has been drawn and AUC was calculated. The result shows that LBP achieves better performance with both CASIA and UBIRIS databases compared to PCA. The experiment has been extended by varying the dataset sizes. The result has shown that LBP outperforms PCA with both CASIA and UBIRIS.

**Keywords:** Local binary, component analysis, databases

### 1. Introduction

The authentication of a person is of high importance in modern days [1]. Other than passwords and magnetic cards, authentication using biometric system is based on bodily or behavioural characteristics of a person. The physical characteristics such as palm print, finger print, face and iris recognition are proved to be accurate and fast. These characteristics are unique to an individual and remain stable through life, and the pattern variability is high among different persons make iris very fascinating for use as biometric system.

A biometric system enables the identification of a person using distinct feature or characteristic exhibited individual person. The Biometric systems are designed for recognition by taking various physical traits as input such as palm prints, finger prints, face, and the iris [2].

### Related Work

The iris is the coloured circle located around the pupil which includes number of randomly distributed structures which are not mutable and hence iris are distinct from another [3]. The past of iris biometrics recognition system is considered as roughly from 2001 [4]. The original algorithm for iris identification works with analysis of texture [5]. The algorithm uses codes which are generated using two dimensional Gabor wavelet. The accuracy achieved is more compared to other methods. The important work done by Wildes [6] has adopted algorithm which uses isotropic band-pass decomposition generated by the application of Laplacian Gaussian filters to the image. This approach has modelled the eyelids using parabolic arcs. Boashash and Boles [7] have proposed a method which has adopted zero-crossings. The zero crossings of the wavelet transform are calculated at different resolutions of circles of the iris which concentric. The single dimensional signals are compared with the features with the help of various dissimilarity functions. Same kind of approach has been presented which has adopted discrete dyadic wavelet transform and showed better efficiency [8]. The Multi-resolution Independent Component Identification (M-ICA) has good ability to use signals along with time frequency to generate the iris features. The accuracy obtained is low since the M-ICA does not work efficiently with class-separability.

Chen and Yuan have proposed a new approach for generating the features of iris using fractal dimension [9].

The iris part has been divided into small parts and the local fractal dimension features are generated as the iris code. The generated patterns are then matched using the neural networks. Robert *et al.* have proposed an algorithm for achieving localization and extraction. For localization, integrodifferential operators along with a Hough Transform has been adopted and for extraction, emergent frequency has been adopted [10]. Code for iris has been generated using both emergent frequency and instantaneous phase.

Li Ma. *et al.* [11] have adopted Haar-Wavelet transform for features extraction in iris. The transformation has been used on the image to generate a feature vector. To classify the vectors, two approaches namely weight vector initialization and winner selection methods are adopted [12]. The recognition capability of classification methods are dependent on feature quality and the size data used for training. The features are generated from shape and texture of segmented parts. Karu *et al.* [13] presented an approach to

achieve automatic identification of textured parts and the categorization uses statistical measures. The Co-occurrence approach is claimed to be the best for classification of texture by Connors and Harlow [14]. The iris structure can be classified with the help of coherent Fourier spectra using optical transmission [15]. The iris biometric designed by Hamed Ranjzad [16] has adopted Independent Component Analysis (ICA) for feature extraction. Image acquisition is performed at different illumination and noise levels.

### Material and Methods

CASIA and UBIRIS datasets have been used in the experiment. Fig. 1 shows the overall architecture of the work carried out. For feature extraction, two methods have been used and compared. One is Principal Component Analysis (PCA) [17, 18] and another one is Local Binary Pattern (LBP). Support Vector Machine has been used for classification.

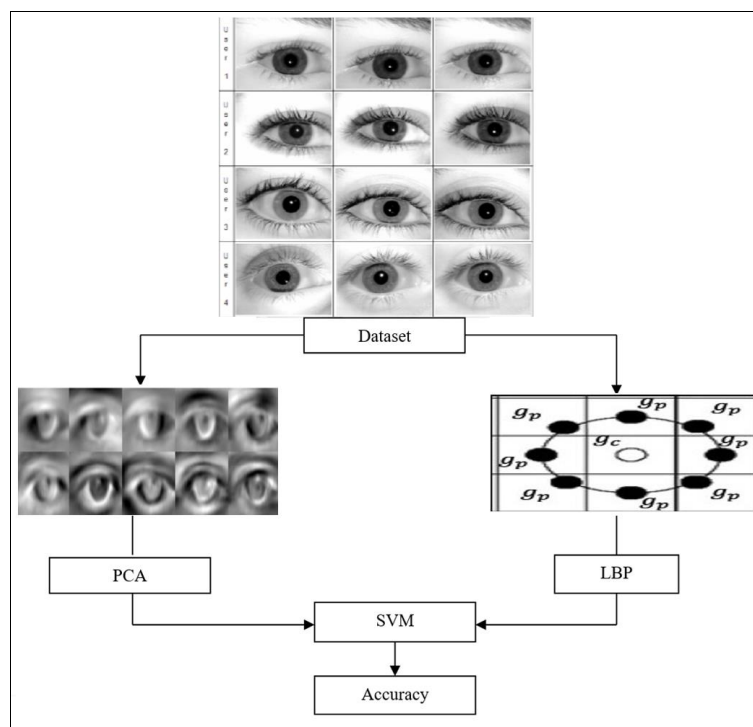

Fig 1: Overall architecture

#### 3.1.1 Principal Component Analysis (PCA)

PCA is one of the most important aspects of linear algebra and it is widely being adopted for analysis purpose. Since it is simple and non-metric method it can be used in neuroscience as well as in computer graphics. PCA guides how to reduce a high dimension data to a lower dimensional data to explore only the sufficient and important features.

The important aspect of PCA is to minimize the dimensionality of a data consisting of a large number of correlated variables and retaining only the important features of data. This is achieved by converting the data to a set of variables called the principal components (PCs). These PCs are independent and are arranged so that the first few components represent the most important features present in all of the original variables.

#### 3.1.2 Local Binary pattern

The number of methods has been developed to extract the useful features from iris images to perform iris biometric

recognition. Local Binary Pattern (LBP) [19, 20] is one among them. LBP makes it possible to represent the image texture and shape.

Fig 2: Local Binary Pattern

The LBP operator was originally proposed by Ojala *et al.* [21]. The LBP operator uses pixel's neighbours and takes the centre pixel value as a threshold as shown in Fig. 2. If a neighbour pixel has a larger gray value than the centre pixel then a one is assigned to that pixel otherwise it takes a zero. The LBP code for the centre pixel is evaluated by

combining the eight binary digits to a code.

The value of the LBP code of a pixel ( $X_c, Y_c$ ) is given by Eq. (1) and Eq. (2)

$$LBP_{M,N} = \sum_{m=0}^{M-1} l(g_m - g_c) 2^m \quad (1)$$

$$l(x) = \begin{cases} 1, & x \geq 0; \\ 0, & \text{otherwise} \end{cases} \quad (2)$$

### Support Vector Machine (SVM)

A SVM [22] which is used to classify data which are linearly separable is called linear SVM which is depicted in Fig. 3. Linear SVM searches for a hyper-plane with the maximum margin. This is why a linear SVM and hence called as a maximal margin classifier (MMC). Steps involved in finding the Maximum Margin Hyper-plane are discussed below:

1. Consider a problem of binary classification consisting of  $n$  training data.
2. Each tuple is represented by  $(X_i, Y_i)$  where  $X_i = (x_{i1}, x_{i2}, \dots, x_{im})$  corresponds to the attribute set for the  $i^{\text{th}}$  tuple (data in  $m$ -dimensional space) and  $Y_i \in \{+, -\}$  denotes its class label.

3. Given  $\{(X_i, Y_i)\}$ , a hyper-plane is generated which separates all  $X_i$  into two sides of it.
4. Consider a two dimensional training data with attributes  $A_1$  and  $A_2$  as  $X = (x_1, x_2)$ , where  $x_1$  and  $x_2$  are values of attributes  $A_1$  and  $A_2$ , respectively for  $X$ .
5. Equation of a plane in 2-D space can be written as

$w_0 + w_1x_1 + w_2x_2 = 0$  [e.g.,  $ax + by + c = 0$ ] where  $w_0, w_1$ , and  $w_2$  are some constants defining the slope and intercept of the line.

Any point lying above such a hyper-plane satisfies

$$w_0 + w_1x_1 + w_2x_2 > 0$$

Similarly, any point lying below the hyper-plane satisfies

$$w_0 + w_1x_1 + w_2x_2 < 0$$

6. An SVM hyper-plane is an  $n$ -dimensional generalization of a straight line in two dimensions.
7. Euclidean equation of a hyper-plane in  $R_m$  is  $w_1x_1 + w_2x_2 + \dots + w_mx_m = b$  (3) where  $w_i$ 's are the real numbers and  $b$  is a real constant.
8. In matrix form, a hyper-plane thus can be expressed as  $W.X + b = 0$  (4) where  $W = [w_1, w_2, \dots, w_m]$  and  $X = [x_1, x_2, \dots, x_m]$  and  $b$  is a real constant.

### Results and Discussion

100 intruder and 100 genuine iris images have been used to conduct the experiment. The True Positive Rate (TPR),

False Positive Rate and Accuracy have been presented in Table 1. The accuracy has been evaluated over different probability threshold values.

Table 1: Accuracy for different probability threshold

The ROC-Curve has been drawn for different combinations of methods and databases. Fig. 4 shows the ROC curves.

**Fig 4:** ROC-Curves

The Area under curve (AUC) has been calculated for different combinations of feature extraction methods and

classification methods along with two databases listed. The result obtained is presented in Table 2.

**Table 2:** Area under curve (AUC)

| Method             | AUC    |
|--------------------|--------|
| PCA + SVM + CASIA  | 0.9125 |
| PCA + SVM + UBIRIS | 0.5518 |
| LBP + SVM + CASIA  | 0.9395 |
| LBP + SVM + UBIRIS | 0.8962 |

The experiment has been conducted using different dataset size. The result obtained is presented in Table 3 and Fig. 5. For different data set size, the accuracy remains high for the

combinations PCA + SVM + CASIA, LBP + SVM + CASIA and LBP + SVM + UBIRIS.

**Table 3:** Accuracy and AUC for different dataset size

| Method             | Dataset size |        |          |        |          |        |          |        |

**Fig 5:** Accuracy graph

## Conclusion

Experiment has been conducted to test the performance of PCA and LBP with two popular iris databases CASIA and UBIRIS. The models were tested using 200 iris images. In case of LBP, the AUC values obtained are 0.8962 and 0.9395 for CASIA and UBIRIS datasets respectively. In case of PCA, the AUC values are 0.9125 and 0.5518 for CASIA and UBIRIS datasets. The result shows that LBP achieves better performance with CASIA and UBIRIS compared to PCA. The experiment was extended for different dataset sizes of 400, 600 and 800. The result shows that LBP outperforms PCA with both CASIA and UBIRIS datasets.
